Abstract

Nonlinear optical (NLO) properties of N-substituted *p*-nitroaniline molecule, N-[(Naphthalen-5-yl)methyl]-4 nitrobenzamine has been calculated theoretically. The theoretical calculations were performed at B3LYP/6-31G(d,p) level. It exhibits large first static hyperpolarizability. The optical response of this molecular system is compared with that of *p*-nitroaniline, which is an excellent NLO dye. The result shows that, naphthalene derivatives of *p*-nitroaniline, exhibit large hyperpolarizability than *p*-nitroaniline and hence can be recommended for photovoltaic device fabrication.

1.Introduction

Nonlinear optical materials are having immense applications in recent years due to their potential use in the fields like laser technology, optical communication, optical data storage and optical signal processing [1–3]. It is also contributing a number of applications in the area of optoelectronics and photonic technologies [4,5]. It becomes a great challenging for physicists and chemists to identify a new class of NLO materials which should fulfill the needs

Selection and peer-review under responsibility of the scientific committee of the Advances in Photoresponsive Materials.

of the above fields. The search for finding the new and better NLO materials having high transparent window in visible region, high optical damage threshold and good optical frequency conversion efficiency have been engaged by several scientists. In this context, variety of organic, inorganic and semi organic NLO materials has been proposed.

Organic chromophores exhibit high and fast nonlinearities and are considered to be potential alternative to the inorganic materials [6,7]. This is because of their tendency to induce delocalization of Π electron. The design of efficient organic materials for the applications in non-linear optical effect is based on asymmetric polarization induced by electron donor and electron acceptor groups on either side of the molecule at appropriate positions in the molecular systems. The structural flexibility of these organic materials permit to easily modify the chemical composition in a precise manner to induce acentric packing which results in large hyperpolarizability (β) and remarkable second order NLO activity (χ 2) [8,9]. The so-called push pull organic molecular systems have been drawn much attention and large number of publications were appeared in the literature [10–17].

p-Nitroaniline is one of the simplest molecules having electron donor and acceptor system connected by an aromatic ring and shows remarkable solvatochromism [18, 19] and large NLO properties [20, 21]. Numerous studies have been reported about these and other photochemical features of p-nitroaniline [22 – 26]. NLO studies on N-substituted p-nitroaniline are being done to improve its nonlinear response.

The principal aim of this work is to undertake an exhaustive theoretical investigation on the structural, electronic and optical properties of N-substituted *p*-nitroaniline. The molecules with large hyperpolarizability values can be developed into NLO materials which are having wide applications in information technology and industry. The molecules chosen for the present study is N-[(Naphthalen-5-yl)methyl]-4- nitrobenzamine.

2.Computational Details

Gaussian 09 software package was used for DFT calculation and calculations were performed at B3LYP/6-31G(d,p) level. The ground state structure was optimized and frequency calculations were performed to ensure that the optimized structure is minimum in the potential energy surface. Electric dipole moment, linear polarizability and first hyperpolarizability tensor components for the studied compounds were calculated by DFT approach which is currently one of the ultimate procedures for obtaining numerically accurate NLO responses. Gauss View 5 software was used for generating the input file and visualization of the results. The calculation were done using S20D300 workstation computer equipped with Intel 7 core processor and 24 GB RAM and Microsoft Windows as the operating system

3.Results and Discussion

3.1. Geometry Optimization

Several conformational isomeric *cisoid* and *transoid* structures of N-[(Naphthalen-5-yl) methyl]-4 nitrobenzamine was optimized at B3LYP/6-31G(d,p) level. The lowest energies of *cisoid* and *transoid* conformations of N-[(Naphthalen-5-yl) methyl]-4 nitrobenzamine are enlisted in Table 1. The lowest energy *cisoid* conformation is 3.02 KJ/mol less in energy than *transoid* conformation. But the conversion of *cisoid* to *transoid*, involves a rotation of C-O bond of naphthyl ether require much higher energy, 36.70 KJ/mol. Hence N-[(Naphthalen-5-yl) methyl]-4 nitrobenzamine shows *cisoid* conformation, the optimized geometry of which is shown in Fig. 1.

3.2. Frontier Molecular Orbitals (FMOs)

The energies of Frontier Molecular orbitals *viz*. HOMO and LUMO, are helpful in investigating the electrical and chemical properties of substrates [27,28].Fig. 2depicts the HOMO and LUMO of the title molecule obtained using B3LYP functionals and 6-31G(d,p) basis set. Though Frontier Molecular orbitals extends over entire molecule,

electron population analysis reveals that HOMO predominates over naphthalene ring whereas its LUMO resides over nitro phenyl part.

Table 1. Total energy an	nd HOMO-LUMO	gaps of N-[(Naj	ohthalen-5-vl) i	methyl]-4 nitro	benzamine

Fig. 2: (a) HOMO (b) LUMO of N-[(Naphthalen-5-yl)methyl]-4-nitrobenzamine

The nonlinear optical response of an isolated molecule in an electric field E_i can be presented as a Taylor series expansion of the total dipole moment, μ_{tot} , induced by the field:

Where, α is the linear polarizability, μ_0 the permanent dipole moment and β is the first hyperpolarizability tensor components. The isotropic (or average) linear polarizability and anisotropy of polarizability is defined as [29]: Isc

peropic linear Polarizability,
$$\langle \alpha \rangle = \frac{1}{3} (\alpha_{xx} + \alpha_{yy} + \alpha_{zz})$$
 (2)

Anisotropic linear Polarizability,
$$\Delta \alpha = \frac{1}{2} [(\alpha_{xx} - \alpha_{yy})^2 + (\alpha_{xx} - \alpha_{zz})^2 + (\alpha_{yy} - \alpha_{zz})^2]^{\frac{1}{2}}$$
(3)

First order Hyperpolarizability $\beta_{tot} = [(\beta_{xxx} + \beta_{xyy} + \beta_{xzz})^2 + (\beta_{yyy} + \beta_{yzz} + \beta_{yyx})^2 + (\beta_{zzz} + \beta_{zxx} + \beta_{zyy})^2]^{\frac{1}{2}}$ (4)

Dipole moment, isotropic polarizability, anisotropic polarizability and hyper polarizabilities of pnitroaniline and N-[(Naphthalen-5-yl)methyl]-4-nitrobenzamine are calculated using the aforementioned equation and were enlisted in Table 2.

real for the former of former and the former of former of the former of							
Molecule	μ	<α> a.u	Δα a.u	β _{tot} a.u.			
<i>p</i> -nitroaniline	7.1564	86.35	134.16	1254.97			
N-[(Naphthalen-5-yl)methyl]-4-nitrobenzamine	7.3012	199.23	191.73	2518.743			

	Table 2: NLO properties of	<i>p</i> -nitroaniline and N-[(Naphthalen-	5-yl)methyl]-4-nitrobenzamine
--	----------------------------	--	-------------------------------

It is clear that hyperpolarizability of *p*-nitroaniline can be improved by adding substituent at N-terminal and hence those molecular frameworks can be considered as good NLO dyes and have potential applications in frequency conversion, image processing, data storage, fiber optic communication etc.

Conclusion

Nonlinear optical (NLO) properties of N-substituted p-nitroaniline molecule, N-[(Naphthalen-5-yl)methyl]-4 nitrobenzamine has been calculated theoretically. The theoretical calculations were performed at B3LYP/6-31G(d,p) level. It exhibits large first static hyperpolarizability. The optical response of this molecular system is compared with that of *p*-nitroaniline, which is an excellent NLO dye. The result shows that, naphthalene derivatives of p-nitroaniline, exhibit large hyperpolarizability than p-nitroaniline and hence can be recommended for photovoltaic device fabrication.

Nonlinear optical (NLO) properties of N-[3-(naphthalene-1-yloxy)butyl]-4-nitroaniline and N-[3-(naphthalene-1-yloxy)butyl]-2,4-dinitroaniline have been calculated theoretically. Theoretical calculations were performed with four different hybrid density functional theories (DFT) *i.e.* BPV86, B3LYP, LSDA and M-06 with 6-31++G(d,p) basis set. The results showed that these molecular systems have large first static hyperpolarizabilities. Moreover, NLO response of these molecular systems decreased considerably when nitrophenyl is replaced by dinitrophenyl group.

Keywords: Nonlinear optical, Hyperpolarizability, Mono-/Dinitroaniline, DFT.

INTRODUCTION

Nonlinear optical (NLO) materials play a vital role in nonlinear optics and have a great impact on information technology and industrial applications. Theoretical calculations play a significant role in understanding the polarization mechanism of NLO materials and their relation to structural characteristics. Last decade witnessed the development of new nonlinear optical materials of inorganic, organic and semi-organic types. Organic nonlinear optical materials have potentially high nonlinearities and rapid response to light [1-4]. They offer high degree of synthetic flexibility to tune their optical properties through structural modification [5]. Organic frameworks with large delocalized π -systems have proven to be useful. This is attributed to the fact that π -electrons are more easily affected by an external optical field as they are relatively loosely bound to the nucleus and that the delocalized orbitals may be extended over the entire molecule giving large and fast polarization [6-9]. The delocalization of π -electrons can be further enhanced by the addition of donor and accepter groups at the opposite ends of the conjugated system. The strong charge transfer between such groups operating across the entire system considerably adds to the optical nonlinearity of structure [10-12]. The large value of first hyperpolarizability (β), which is the measure of nonlinear optical activity, is attributed to intramolecular charge transfer which occurs due to the movement of electron cloud from electron donor to acceptor groups through a π conjugated framework [13-16]. The designing of new nonlinear optical materials relies heavily on the theoretical prediction of accurate electro-optical properties for aforementioned systems.

The polarizability of organic frameworks containing naphthalene has been extensively studied with different theoretical methods and found to have good nonlinear response. An efficient method to modulate electron density distribution in this conjugated system is the incorporation of functional groups (spacers) into its backbone. Such studies are done on conjugated oligomers and polymers [17,18]. But donor-acceptor systems containing naphthalene incorporated with spacer groups in the backbone are largely unexplored.

The principal aim of this work is to undertake an exhaustive theoretical investigation on the structural, electronic and optical properties of naphthalene framework linked to nitrophenyl group through a spacer groups. The molecules with large hyperpolarizability values can be developed into NLO materials which are having potential applications in the optoelectronic devices of telecommunications, information storage, optical switching and photovoltaic devices like solar cells. We propose to investigate molecules in which naphthalene group is connected to mono-/

di-nitrophenyl groups in which the linking groups are saturated carbon chain. The molecules chosen for the present study are N-[3-(naphthalene-1-yloxy)butyl] -4-nitroaniline (1) and N-[3-(naphthalene-1-yloxy)butyl]-2,4-dinitroaniline (2) (Fig.1).

COMPUTATIONAL METHODS

Gaussian 09 software package was used for DFT calculation and the calculations were performed at four different hybrid density functional theories (DFT) i.e. BPV86, B3LYP, LSDA and m-06 and 6-31++G(d,p) basis set was used. The gound state structures were optimized and frequency calculations were performed to ensure that the optimized structures are minima in the potential energy surface. HOMO and LUMO for all the molecules are identified. Gauss View 5 software was used for generating the input file and visualization of the results. The calculation were done using S20D300 workstation computer equipped with Intel 7 core processor and 24 GB RAM and Microsoft Windows as the operating system. Electric dipole moment, linear polarizability and first hyperpolarizability tensor components for the studied compounds were calculated by DFT approach which is currently one of the ultimate procedure for obtaining numerically accurate NLO responses.

RESULTS AND DISCUSSION

Geometry optimization: The optimized molecular geometry represents an isolated molecule under ideal conditions with a stationary point at the potential energy surface. The convergence was confirmed by observing no imaginary vibrational frequencies. The optimized geometries of compounds 1 and 2 are shown in Fig. 2. Theoretical studies revealed that the compound 1 exists in transoid conformation whereas compound 2 exists in cisoid conformation. Analysis of the optimized geometries derived the following observation regarding the structure. The naphthalene part is coplanar with spacer group while the nitrophenyl part of the framework is twisted with respect to the spacer (Fig. 3). This conclusion is supported by the relevant torsional angles listed in Table-1.

Frontier molecular orbitals (FMOs): The energies of frontier molecular orbitals *viz*. HOMO and LUMO, are helpful in investigating the electrical and chemical properties of substrates [19,20]. Fig. 3 depicted that the HOMO and LUMO orbitals for compounds 1 and 2 obtained using B3LYP functionals and 6-31++G(d,p) basis set. The HOMO and LUMOs for two compounds are observed to be identical. HOMO of both compounds

Fig. 3. HOMO and LUMO orbitals for compounds 1 and 2

1 and 2 extends over naphthalene donor moieties, whereas LUMO of both compounds 1 and 2 resides over dinitrophenyl part.

Using the ground state HOMO and LUMO energies, the chemical hardness (η), the electronic chemical potential (μ) and the global electrophilicity index (ω) have been estimated and the calculated values are listed in Table-1.

	TABLE-1						
GRO	DUND STAT	E HOMO A	ND LUM	O ENER	GIES, TH	ŧΕ

POTE	ENTIAL (II) /	AND THE G	LOBAL F	ELECTRO	OPHILIC	ITY	
1011	$\frac{10121}{1012} (\mu) \frac{100}{100} \frac{100}{10$						
	INDEA			SIANL	- 2		
C 1	HOMO	LUMO	E				
Compd. (a.u.) (a.u.) (eV) η μ ω							
1	-0.20422	-0.07029	3.64	1.82	3.73	3.83	
2	-0.21101	-0.09895	3.04	1.52	4.22	5.84	

Chemical reactivity: The kinetic stability of aforementioned compounds can be monitored by HOMO-LUMO energy gaps [21]. Smaller HOMO-LUMO energy gap leads to lower kinetic stability and higher chemical reactivity. All the present results showed that compound **2** is much more reactive than compound **1**. The chemical reactivity description parameter like chemical hardness (η) is useful in studying the stability and reactivity of compounds. It is given in terms of the energies of HOMOs and LUMOs [22]:

$$\eta = \left(\frac{E_{HOMO} - E_{LUMO}}{2}\right) \tag{1}$$

This formula indicates that the soft compounds have small chemical hardness, while hard ones have large chemical splitting. The electronic chemical potential (μ) shows the escaping tendency of electrons in compounds [23] and given by eqn 2 [24,25]:

$$\mu = -\left(\frac{E_{HOMO} + E_{LUMO}}{2}\right) \tag{2}$$

The global electrophilicity index (ω) estimates the stabilizing energy when a surrounding environment supplies a chemical entity with an additional electronic charge. The index (ω) relates to the electronic chemical potential (μ) and the chemical hardness (η) through eqn 3 [23]:

$$\omega = \frac{\mu^2}{2\eta} \tag{3}$$

The values of global electrophilicity indexes have been calculated and presented in Table-1. It is evident that compound 1 is the stronger nucleophile than compound 2. It implies that the electron density over compound 1 becomes more polarized towards external optical response. Consequently, the degree of delocalization increases which results in higher hyperpolarizability.

Optical activity: First order polarizability of naphthalene were studied by Hincliffe *et al.* [26,27] and Howard *et al.* [28] using different methods and basis sets. In the present study, polarizability of naphthalene is calculated at DFT level using different basis sets. All calculated and experimental values [29] of first order polarizability of naphthalene are enlisted in Table-2.

TABLE-2								
FIRST ORDER POLARIZABILITY OF NAPHTHALENE								
AT DIFFER	ENT LEVE	LS OF THE	EORY					
Model chemistry	α _{xx}	α _{yy}	α_{zz}	<0>> (au)				
B3LYP/6-31G(d,p)	143.66	122.81	33.31	99.92				
B3LYP/6-311G(d,p)	149.41	127.73	43.09	106.74				
B3LYP/6-31+G(d,p)	156.32	133.74	61.53	117.19				
B3LYP/6-31++G(d,p)	156.39	133.81	62.21	117.47				
B3LYP/6-311+G(d,p)	156.30	133.64	61.86	117.26				
B3LYP/6-311++G(d,p)	156.37	133.70	61.96	117.34				
B3LYP/6-311++G(2d,p)	158.35	135.49	64.25	119.37				
M-06/6-31+G(d,p)	144.62	123.89	33.59	100.71				
Experimental value				117.40				

It is clear that the mean polarizability value calculated using 6-31++ G(d,p) is in close agreement with experimental value which is available from literature [29]. So DFT method with 6-31++G(d,p) basis set is selected for NLO calculations. Optical properties such as dipole moment, isotropic linear polarizability $<\alpha$ >, anisotropic linear polarizability ($\Delta\alpha$) and first order or static hyperpolarizability (β) were calculated using different functionals BPV86, B3LYP, LSDA and M-06. BPV86 uses Perdew's 1986 functional with local correlation replaced by that which was suggested by Vosko *et al.* [30]; B3LYP is Becke's three parameter exchange functional and the gradient corrected functional of Lee, Yang and Parr [31]; LSDA is the Local Spin Density Approximation and M-06 is Minnesota functional.

The nonlinear optical response of an isolated molecule in an electric field E_i can be presented as a Taylor series expansion of total dipole moment (μ_{tot}) induced by the field:

$$\begin{split} \mu_{\lambda} &= \left\langle \psi(E) \left| \hat{\mu}_{\lambda} \right| \psi(E) \right\rangle \\ \mu_{\lambda} &= \mu_{\lambda}^{0} + \alpha_{\lambda\sigma} E_{\sigma} + \frac{1}{2!} \beta_{\lambda\sigma\nu} E_{\sigma} E_{\nu} + \frac{1}{3!} \gamma_{\lambda\sigma\nu\rho} E_{\sigma} E_{\nu} E_{\rho} + \dots, \end{split}$$

where, α is the linear polarizability, μ_0 is the permanent dipole moment and β is the first hyperpolarizability tensor components. The isotropic (or average) linear polarizability and anisotropy of polarizability [32] is defined as follows:

Isotropic linear polarizability:

$$\langle \alpha \rangle = \frac{1}{3} (\alpha_{xx} + \alpha_{yy} + \alpha_{zz})$$

Anisotropic linear polarizability:

$$\Delta \alpha = \frac{1}{2} \Big[(\alpha_{xx} - \alpha_{yy})^2 + (\alpha_{xx} - \alpha_{zz})^2 + (\alpha_{yy} - \alpha_{zz})^2 \Big]^{1/2}$$

The complete equation for calculating the total static first hyperpolarizability magnitude of Gaussian output [34] is given as follows:

First order hyperpolarizability:

$$\beta_{tot} = \left[(\beta_{xxx} + \beta_{xyy} + \beta_{xzz})^2 + (\beta_{yyy} + \beta_{yzz} + \beta_{yxx})^2 + (\beta_{zzz} + \beta_{zxx} + \beta_{zyy})^2 \right]^{1/2}$$

The study involves the initial determination of dipole moment, isotropic linear polarizability, anisotropic linear polarizability and static hyperpolarizibilities in the gas phase. The results are compiled in Table-3.

TABLE-3 DIPOLE MOMENT, ISOTROPIC LINEAR POLARIZABILITY, ANISOTROPIC LINEAR POLARIZABILITY AND STATIC HYPERPOLARIZIBILITIES OF COMPOUNDS 1 AND 2 USING DIFFERENT LEVELS OF THEORY								
Compd.	Parameter	B3LYP	BPV86	LSDA	M-06			
	Dipole moment	6.67	6.67	6.53	6.81			
1	<0>	232.69	242.27	256.81	242.82			
	$\Delta \alpha$ (a.u.)	268.37	289.77	230.35	292.27			
	β_{tot} (a.u.)	2306.04	2474.84	2471.07	2499.03			
	Dipole	7.44	7.47	7.58	7.50			
	moment							
2	<0>	257.07	265.89	266.34	257.22			
	$\Delta \alpha$ (a.u.)	138.60	148.78	150.15	136.62			
	β_{tot} (a.u.)	1467.67	1579.02	1716.43	1125.73			

Calculation results showed that both compounds 1 and 2 have large first hyperpolarizability and consequently have good nonlinear response. Hyperpolarizability of compound 1 is greater than compound 2. The magnitudes of hyperpolarizibilities depend on chemical reactivity and structural characteristics of the molecule. Degree of electron delocalization between the two rings, naphthalene and nitrophenyl, has an important role in increasing the hyperpolarizibilities. Optical response properties are governed by the increasing of both conjugation length and strength of donor and acceptor groups, planarity of rings with spacer. Degree of electron delocalization between the two rings can be monitored by measuring effective distance between relevant atoms of two rings (C7-C15) and coplanarity can be assessed by the torsional angles between the planes of donor and acceptor subunits (angle between C11-O1-C7-C8 and angle between C17-C15-N1-C14). The aforementioned geometrical parameters (Fig. 1) obtained from the optimized geometries (Fig. 1). The torsional angles and effective distance between two rings are given in Table-4.

It is evident that the effective distance between two rings for mononitro derivatives are larger than dinitro derivatives. As the effective distance increases, it is believed that the extent of delocalization increases. So mononitro compounds are having large β values than dinitro compounds.

TABLE-4	
COMPARISON OF FIRST HYPERPOLARIZABILITY FOR COMPOUNDS A AND B USING	
B3LYP, BPV86, LSDA AND M-06 AND SOME SELECTED GEOMETRICAL PARAMETERS	

Compd. No.	β (B3LYP)	β (BPV86)	β (LSDA)	β (M-06)	C7-C15 (Å)	C17-C15-N1-C14 (°)	C11-O1-C7-C8 (°)
1	2026.33	2223.519	2271.065	1891.24	6.89	-6.3	1.273
2	1467.674	1579.016	1716.427	1125.73	4.503	-10.91	2.434

Conclusion

Nonlinear optical (NLO) properties of N-[3-(naphthalene-1-yloxy)butyl]-4-nitroaniline (1) and N-[3-(naphthalene-1vloxy)butyl]-2,4-dinitroaniline (2) have been calculated theoretically using four different hybrid density functional theories (DFT) *i.e.* BPV86, B3LYP, LSDA and M-06 and 6-31++G(d,p)basis set was used. The results showed that these molecular systems have large first static hyperpolarizabilities. In addition, NLO response of these molecular systems decreases dramatically when nitrophenyl is replaced by dinitrophenyl group. This can be attributed to their chemical reactivity and structural characteristics. Firstly, compound 1 is more nucleophilic than compound 2 and hence there is a greater delocalization. Secondly, the extent of delocalization has been reaffirmed by the effective distance between two rings, which is greater for compound 1. Finally, naphthalene ring of compound 1 is more coplanar to spacer group than compound 2, which enhances the delocalization. Since both the compounds chosen for the present study are reported to have a high hyperpolarizability, they can be used for developing NLO materials.
